Other CAD programs use a similar naming convention. AutoCAD files A CAD file is typically called with an extension of either dxf or dwg. Each file type has a command that can be used to edit the file. As each application understands only a limited subset of the data in a file, additional information to the file data is embedded in the file name, in the form of a data dictionary. The dictionary is in a file named dataDictionary.xml. Police say that one of the incidents occurred at a residence in Port Alberni on Wednesday evening. A man and a woman were arrested there and were found to be in possession of stolen property, including two computers. They say that the pair will likely be charged with multiple break-and-enters and stolen property offences. They also note that after two of the incidents, a man and a woman were observed driving a white SUV and have been asked to provide a DNA sample. They say that it's unknown at this time whether they were connected to the crimes, and additional charges will be sought if and when the investigation determines that the two are connected. One of the principal storage devices used today is the disk drive. Disk drive units, and more specifically hard disk drives, store information on circular magnetic platters. The platters are mounted to a rotating hub. The hub is attached to a spindle motor. The platters are rotated at high speed and a read-write head is actuated to read and write data to the platters. An actuator operates within a closed loop servo system. The actuator has a plurality of arms. The arms include a voice coil located near the platters. The voice coil is moved by an actuator coil motor in response to the changing current through the actuator coil motor. The spindle motor rotates the platters as the actuator coil motor moves the voice coil. The actuator controller controls the actuator coil motor in response to signals from a pre-amplifier. The pre-amplifier receives the signals from a read-write head which is located at the end of one of the arms. The pre-amplifier is typically located near the voice coil. Data from the pre-amplifier is amplified and demodulated by a read channel located in the actuator controller. The actuator controller is normally implemented with a read channel circuit and a microprocessor. The microprocessor is used to monitor the position of the read-write head and write data to the actuator coil motor. A position encoder is also connected to the microprocessor. The position encoder provides digital information to the microprocessor regarding the position of the read-write head. The microprocessor controls the actuator coil motor to move the read-write head to the appropriate track on the platter. The microprocessor then reads the data from the read-write head. The data is then processed by the microprocessor. When power is first applied to the hard disk drive, the actuator coil motor is not operating. The actuator controller must therefore wait a period of time before it can determine the position of the read-write head. Typically, the actuator controller can determine the position of the read-write head only after two revolutions of the platters have occurred. This is referred to as two full revolutions of the platters. After the read-write head
